

# Rotational Velocity in the Milky Way

March 27, 2025

## Abstract

In this report we present a model for the rotation of stars in the Milky Way around its center. In a first simpler model, we are going to assume that the stars in the GC (Galactic Center) frame move in circular orbits around its origin with a constant velocity  $V_{rot}$ , as well as the LSR (Local Standard of Rest), and that the Sun frame is moving with a velocity  $U_\odot$  in the x-direction and  $V_\odot$  in the y-direction in the GC frame with respect to the LSR. Then, we will present a second, more complex model, in which we will add to the simpler one a random component of the radial velocity  $v'_{rand} \sim N(0, \sigma^2)$ .

In this report, we used the data provided by GAIA DR2 [1], considering, for each star on the galactic plane, its longitude, parallax, and radial velocity, along with the respective uncertainties.

The data will be used to make Bayesian inference on the parameters of the two models, namely  $\theta_1 = (V_{rot}, U_\odot, V_\odot)$  and  $\theta_2 = (V_{rot}, U_\odot, V_\odot, \sigma)$ , using MCMC (Monte Carlo Markov Chain) to estimate their non-normalized probability distribution.

## 1 Model

### 1.1 Physical Model

GAIA provides measurements of the radial velocity relative to the Sun's frame of reference. In our model, the Sun's frame moves around the center of the galaxy with a drift velocity (that of the LSR) plus a random vector. In the following, primed vectors are in the frame of reference of the Sun, whereas unprimed ones are in the frame of reference of the center of the galaxy. Angles are supposed to be expressed as radians. Calling  $\mathbf{v}_0$  the total velocity of the Sun relative to the center of the galaxy, we have the following relation:

$$\mathbf{v}_0 = \mathbf{v}_{LSR} + \mathbf{v}_{rand} \quad (1)$$

We can fix the frames of reference in the center of the Galaxy and on the Sun as in fig.1. In the picture, all the velocities are represented in the frame of reference fixed at the center of the galaxy. In our model, in this frame, all the stars (and the LSR frame) move around the center with velocity  $V_{rot}$ , therefore, the velocity for a star  $s$  at angle  $\varphi$  from the x-axis is:

$$\begin{aligned} \mathbf{v}_s &= V_{rot}(-\hat{e}_\varphi) \\ \hat{e}_\varphi &= \begin{pmatrix} -\sin(\varphi) \\ \cos(\varphi) \end{pmatrix} \end{aligned} \quad (2)$$

In particular, we fix  $\varphi = \pi$  for the Sun. Therefore, the velocity of the Sun, in the rest frame of the Galaxy is given by the equation:

$$\mathbf{v}_0 = \begin{pmatrix} 0 \\ V_{rot} \end{pmatrix} + \begin{pmatrix} U_0 \\ V_0 \end{pmatrix} \quad (3)$$

The frame of reference of the sun is moving with velocity  $\mathbf{v}_0$  given by eq.1, and its axis are rotating with an angular velocity  $\mathbf{w}_{sun} = -w_{sun}\hat{e}_z$ . Therefore, the velocity  $\mathbf{v}'_s$  of a star  $s$  at distance  $d$  from the Sun is given by the equation

$$\mathbf{v}'_s = \mathbf{v}_s - \mathbf{v}_0 - \mathbf{w}_{sun} \times \hat{e}'_r d = \mathbf{v}_s - \mathbf{v}_0 + w_{sun} \hat{e}'_l d \quad (4)$$

The radial component of the velocity of a star with longitude  $l$  in the sun frame of reference is finally given by:

$$\begin{aligned} \hat{e}'_r &= \begin{pmatrix} \cos(l) \\ \sin(l) \end{pmatrix} \\ v_s^{rad'} &= \mathbf{v}'_s \cdot \hat{e}'_r = \\ &= V_{rot} \left[ \sin \varphi \cos l - (1 + \cos \varphi) \sin l \right] - U_0 \cos l - V_0 \sin l \end{aligned} \quad (5)$$

Figure 1: Frames of reference.

Eq.5 must be adapted to the actual data provided by GAIA, which means expressing  $\sin \varphi$  and  $\cos \varphi$  in terms of  $l$  and the parallax  $p$ , expressed in arcseconds. First of all, the distance in parsec can be computed as:

$$d[pc] = \frac{1000}{p[arcsec]} \quad (6)$$

Then, by applying the cosine theorem two times for  $R, d, D, l, \varphi$  (fig.1),  $\cos \varphi$  can be written as:

$$\cos \varphi = \frac{d \cos l - R}{\sqrt{d^2 + R^2 - 2dR \cos l}} \quad (7)$$

and, therefore,

$$\sin \varphi = \pm \sqrt{1 - \cos^2 \varphi} = \frac{d \sin l}{\sqrt{d^2 + R^2 - 2dR \cos l}} \quad (8)$$

By substituting eq.6-8 into eq.5, we get an expression for the prediction of the model for the radial component of the velocity of star  $i$   $v_{rad}^{mod}(l_i, p_i)$  as a function of the measurements of its longitude and parallax  $l_i, p_i$ .

## 1.2 Statistical Model

## 1.3 Uncertainties

GAIA measurements are affected by statistical uncertainties on the evaluations of the parallax and the radial velocity. We as-

sume the measurements to be random variables sampled from a gaussian distributrion centered at the true value of the respective quantity, with standard deviation given by the error reported by GAIA ( $v_{rad} \sim N(\tilde{v}_{rad})$ ). Assuming the pysical model to be exact, and the measurements to be independant, the difference between the direct measure of the radial velocity, and the corresponding value given by the model by eq.5 is a random variable with variance that can be computed through propagation of errors as described in the following.
